About the dataset

The Global Terrorism Database (GTD) is an open-source database including information on domestic and international terrorist attacks around the world from 1970 through 2017, and now includes more than 181,691 cases. For each event, information is available on the date and location of the incident, the weapons used and nature of the target, the number of casualties, and–when identifiable–the group or individual responsible. There are 18,1691 records and 135 columns including date, time, location, number of hostages, killed, wounded, if there was a ransom, the outcome, if there was a suicide attack, claims, weapons used. Unit of analysis: Attack. The number of variables are > 100 on location, tactics, perpetrators, targets, and outcomes.

Global Terrorist Dataset: https://www.kaggle.com/START-UMD/gtd

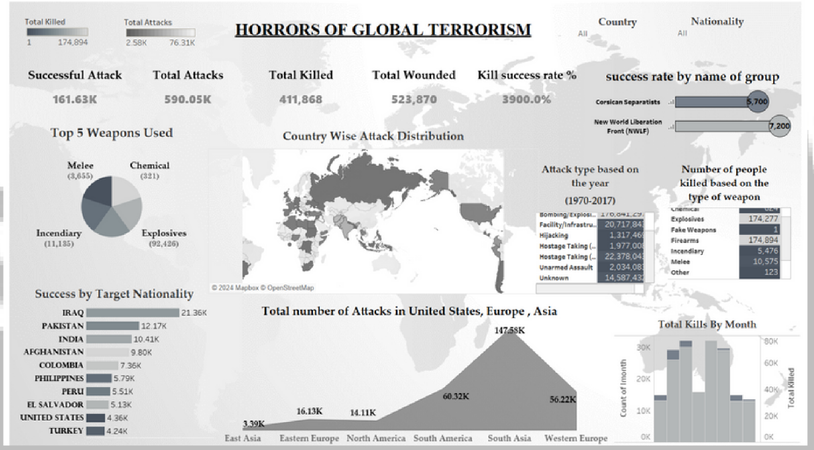
The world is suffering and bleeding day by day. Too many people are dying among both civilians and soldiers. Words are not needed when you know they will not change this horrifying scenario. How can we fight terrorism, then? The answer is participation, the answer is comprehension. The world needs to stay logical, to not fill its heart with anger, because anger carries blindness.
It is evident that there has been enormous growth in terrorist attacks in recent years. As Data Analytics student, we have the tools of data and visualization with us to answer some of the questions which can help to find out trends, patterns, and some interesting insights from this dataset. This can be our contribution to tackling the horrors of global terrorism. Using this data, we can also predict the terrorist attack using machine learning which will help to reduce the feeling of uncertainty as how the terrorist went about planning a major attack undetected, was the terror act an isolated instance or the first of a series, and who were the responsible groups behind such heinous crimes.

Problem:

Through this project, we would like to address the following:

- Demonstrate the available data in a well organized manner to make it understandable
- Find out the countries which were most attacked between 1970- 2018
- Which is the most powerful weapon type
- Total number of incidents in United States, Europe , Asia
- How the terrorist attacks increased or decreased over the years in different regions all over the world?
- What are the main targets of these terrorist attacks?

Based on the insights gleaned from visualization analysis of global terrorism data, we can strategically concentrate security resources and efforts in regions or countries where terrorist activities are most prevalent, thereby enhancing our ability to prevent and respond to potential threats. Additionally, by allocating resources more efficiently based on this analysis, we can maximize the impact of our counter-terrorism measures and ensure that they are directed towards areas with the highest risk. Furthermore, collaborating with international partners and organizations based on the findings of the analysis can facilitate the exchange of information and resources, fostering a more coordinated and effective global response to the challenge of terrorism.



What Went Well:

Data collection was thorough and comprehensive.
Visualizations effectively conveyed key trends and patterns.
The project successfully raised awareness about global terrorism issues.

What Did NOT go Well:

Some data sources were incomplete or outdated, leading to gaps in analysis.
Certain visualizations were overly complex and difficult to interpret for some audience members.
Limited time constraints hindered deeper exploration of certain aspects of the data.

What Would you do Differently Next Time:

Use more reliable and up-to-date data sources to ensure accuracy.
Simplify visualizations to make them more accessible to a wider audience.
Allocate more time for in-depth analysis and exploration of specific trends or regions.
